The relationship between investments in lean practices and operational performance: exploring the moderating effects of operational intellectual capital

Abstract

Purpose - Prior research has shown that operational intellectual capital (OIC) and investments in lean practices (ILP) lead to better operational performance. However, there has been no empirical studies on the synergetic effects between OIC components and ILP. More specifically, the question: can the efficacy of ILP be increased through OIC has not been studied. Accordingly, the purpose of this study is to report the empirical results of potential synergetic effects between operational intellectual capital (OIC), as a knowledge-based resource, and ILP.

Design/Methodology/approach - The empirical data used for this study was drawn from the fifth round of the Global Manufacturing Research Group (GMRG) survey project (with data collected from 528 manufacturing plants). The hypotheses are empirically tested using three ordinary least square (OLS) models.

Findings - Our findings highlight the importance of leveraging a system of complementary knowledge based resources (OIC dimensions) and addresses the need for the reformulation of lean theory in terms of the emergent knowledge-based view (KBV) of the firm. The results facilitate greater understanding of the complex relationship between ILP and operational performance. Building on the contribution of Menor et al. (2007), we argue that OIC represents a strategic knowledge based resource that is valuable, hard to imitate or substitute and when leveraged effectively, generates superior operational and competitive advantage.

Practical implications - From a managerial standpoint, this study provides guidelines for managers on how to leverage OIC to enhance the efficacy of ILP. We argue that firms consider investing in OIC to increase the return from ILP, which in turn will enhance their operational performance and provide competitive advantage. Our findings provide strong evidence of the importance of human, social and structural capital to enhance the efficacy of ILP.

Originality/value - This is the first research paper that extends the application of intellectual capital theory in lean literature, and argues that the operational intellectual capital contributes

1
2
3 to the efficacy of ILP. The analysis facilitates greater understanding of the complex relationship
4 between OIC dimensions, ILP and operational performance.

15 **1. Introduction**

16
17 Lean practices have been adopted by companies across the world and there is a considerable
18 body of work which has investigated the relationship between lean manufacturing adoption and
19 organisational performance (Jasti and Kodali, 2015, Negrão et al., 2016). The objective of lean
20 manufacturing is to maximize customer value while minimizing waste. The ultimate goal of
21 implementing lean production in an operation is to increase productivity, enhance quality,
22 shorten lead times, and reduce cost. Negrão et al. (2016) argue that most of the research to date
23 has focused on the technical aspects of lean (i.e. practice implementation and its effect on
24 performance), rather than the “people” related issues. More recently, researchers have shifted
25 their focus towards “why” lean works (or not), and in particular addressing human resource
26 management (HRM) practices (Vivares-Vergara et al., 2016). For example, Bonavia and Marin-
27 Garcia (2011) note that the majority of recent studies have concentrated on examining the HRM
28 practices needed to sustain lean implementation over time, but little is known as to whether or
29 not the HR function can have a more strategic impact on lean practices. Sparrow and Otaye-
30 Ebede (2014) argue that in order to achieve sustainable lean implementation, companies need
31 to focus on building dedicated and specialised knowledge and creating a broader structural
32 grouping of intellectual capital. Similarly, Reed et al. (2006) contend that knowledge and the
33 management of intellectual capital has become a key factor of growth and sustainability in
34 firms, allowing them to become more adaptable and responsive. Although prior research has
35 shown that intellectual capital (IC) leads to improved organisational performance (Menor et
36 al., 2007, Hsu and Wang, 2012, Lu et al., 2014, Wang et al., 2014), there has been no empirical
37 studies of how intellectual capital influences the implementation of lean practices. More
38 specifically, the question of how specific elements of operational intellectual capital (OIC) can
39 influence the efficacy of lean practices has not been studied.

57
58 In order to improve performance, an organization needs to continuously improve its
59 effectiveness as well as its efficiency. This is possible only through a continuous development
60

1
2
3 of organizational competencies. These capabilities are rooted in the organizational knowledge
4 assets (Ansari et al., 2012), which build the OIC of the organizations (Menor et al., 2007,
5 Schiuma and Lerro, 2008). In a lean implementation, we argue that three dimensions of OIC:
6 human, structural and social capital, will enhance lean investments' performance. Given that
7 organisations accumulate expertise in multiple cycles of knowledge processing (Lee et al.,
8 2011), this research posits that companies need to understand how to leverage different forms
9 of knowledge resources (i.e. OIC dimensions), in order to enhance ILP. According to Teece
10 (2014), knowledge-based resources both explicit and tacit, form competitive advantage. These
11 knowledge-based resources are typically stored in personnel, organizational routines,
12 manufacturing processes and relationships across the supply chain. Eisenhardt and Santos
13 (2003) claim that these knowledge-based resources create competitive advantage because they
14 are rare, valuable and difficult to substitute or imitate.

15
16
17 Proponents of the knowledge based perspective (KBV) (Grant, 1996, Hörisch et al., 2015) posit
18 that knowledge is the most important strategic resource of the firm. In order to sustain their
19 performance, companies need to “manage the system of complementary resources that
20 constitutes its knowledge base” (Menor et al., 2007: p.561). Sparrow and Otake-Ebede (2014)
21 assert that the interactions between operations management (OM) and human resource
22 management (HRM) practices represent a lean philosophy and these have a synergistic effect
23 on the operational performance. Human-related resources has been identified as key to the
24 successful implementation of lean projects and recent studies suggest that OIC plays a critical
25 role in sustainable competitive advantage (Bonavia and Marin-Garcia, 2011, Clegg et al., 2013).
26 According to Ling (2013), OIC is unexplored territory, while Wang et al. (2015) argue that
27 management of OIC has a much bigger influence on employees than previously expected and
28 that lean implementation can depend on employees willingness to adopt these practices.

29
30
31 Accordingly, our study will examine the synergetic effects between OIC dimensions and ILP.
32 Building on the contribution of Menor et al. (2007), we argue that OIC represents a strategic
33 knowledge based resource, that is valuable, hard to imitate or substitute and when leveraged
34 effectively, generates superior operational and competitive advantage. We adopt the
35 Subramaniam and Youndt (2005) definition of OIC as the aggregation of all knowledge
36 embedded in the company's operating resources. OIC comprises three forms of knowledge
37 based resources: human capital (i.e. knowledge, experience and professional skills and abilities
38 of the employees), structural capital (i.e. codified knowledge, databases, patents, manuals,
39 structures, information systems and processes) and social capital (i.e. communications among

3 people and their networks of interrelationships). Lean practices are measured as the ILP (in
4 terms of money, time and/or people) in the previous two years. Lean implementation can be
5 broadly described as a system that encompasses a variety of practices such as: quality
6 management programs (i.e. TQM, six sigma), cost reduction programs (i.e. target costing),
7 manufacturing lead time reduction programs, planning/scheduling processes and methods,
8 processing technologies (e.g. automation, advanced manufacturing technologies), flexible
9 workforce, supplier development, workforce training and development, integrating
10 manufacturing and design processes, the automation of plant information flows, customer
11 service, customer process integration and supplier process integration (Cua et al., 2001,
12 Modarress et al., 2005, Narasimhan et al., 2006, Jayaram et al., 2008, Kull et al., 2014,

23 Our study will address the following research question:

24
25 *Can the efficacy of investments in lean practices be increased through operational intellectual*
26 *capital?*
27

28
29
30 In answering this question, this paper makes three key contributions to operations management
31 literature. Firstly, we extend the application of intellectual capital theory in operations
32 management research, by recognising the structural, social and human dimensions of
33 intellectual capital. Although the belief that intellectual capital leads to better organisational
34 performance is well known, very few empirical studies have tested the impact of individual
35 elements of intellectual capital on operational performance (Menor et al., 2007) Secondly, we
36 build on the lean literature to argue that operational intellectual capital contributes to the
37 efficacy of ILP (Sparrow and Otaye-Ebede, 2014) and the analysis facilitates greater
38 understanding of the complex relationship between lean practices and operational performance.
39 Thirdly, our research offers practitioners insights into the advantages of managing knowledge
40 assets for improved operational performance, as well as highlighting how OIC can be leveraged
41 to enhance operational performance generated through ILP (Wang et al., 2014).

2. Theoretical background and hypotheses development

2.1 The Impact of lean practices on operational performance

Empirical research into lean practices has advanced over the past two decades. Lean management is a holistic business strategy that requires a change in mind set that extends beyond operations. Lean thinking emphasizes excellence through the elimination of waste and a focus on continuous improvement (Fullerton et al., 2014). The literature on lean practices is extensive and numerous empirical studies have examined the impact of lean practices on performance. Much of this empirical work supports a positive relationship between lean practices and performance (Jasti and Kodali, 2015, Negrão et al., 2016). Narasimhan et al. (2006) found that lean companies that outperform their competitors use practices such as six sigma, benchmarking, in-house technology development, customer and supplier orientation, integrated product development, teams and advanced manufacturing technologies. Shah and Ward (2003) examined the key facets of lean manufacturing using 22 manufacturing practices and grouped them in four “bundles” of inter-related and internally consistent practices (just in time (JIT), total quality management (TQM), total preventive maintenance (TPM) and human resource management (HRM)). Their results provided strong support for the contribution of lean bundles to the operating performance of the plants.

However, other studies highlight a negative or non-significant relationship between lean practices and performance measures. For example, Chen and Hua Tan (2013) examined the effect of lean practices in Chinese manufacturing firms and reported that companies (privately owned) experienced no operational improvements (quality and on-time delivery). The authors argued that those companies lacked in managerial resources and advanced management culture. Likewise, Bortolotti et al. (2013) found that JIT supply, single minute exchange die and cell manufacturing had a negative impact on lead time, on-time delivery and flexibility. These results were explained as a product of the high variability of demand within the companies surveyed. Their findings corroborate with literature that highlights the limitations of lean applications in non-repetitive environments.

More recent studies have highlighted the need to investigate how human resources can enhance the effect of lean on operational performance (Bonavia and Marin-Garcia, 2011, Clegg et al., 2013, Boscari et al., 2016, Vivares-Vergara et al., 2016). Companies that achieve the highest payoff from lean practices, are those that train workers and improve their employment security (Bonavia and Marin-Garcia, 2011). In addition, Boscari et al. (2016), highlighted the

1
2
3 importance of teamwork, training and development, workforce adaptation/flexibility and
4 culture on the success of implementation of lean practices.
5
6

7 ~~The literature would appear to suggest that there are inconsistencies in the relationship between~~
8 ~~lean practices and performance. This could be explained through the application of contingency~~
9 ~~theory. This theory suggests that organisations do not exist in isolation, and are influenced by~~
10 ~~organisational and environmental factors. The implication is that firm performance will be~~
11 ~~maximised when there is a fit between an organisation's structure/processes and the external~~
12 ~~environment (Chavez et al, 2015). Applying contingency theory, the lack of an association~~
13 ~~between lean practices and performance may be explained by contextual differences. Most~~
14 ~~empirical studies that have considered contextual factors have been exploratory (Browning and~~
15 ~~Heath, 2009), with only some limited work looking at a firm's internal characteristics, such as~~
16 ~~size differences (Bayo-Mo~~

23
24

25 In summary, ILO helps to standardize operations and results in significant strategic benefits.
26 According to Pakdil and Leonard (2014), lean production methods provide manufacturing
27 organisations with a powerful competitive advantage due to efficient systems that “consume
28 fewer resources, creating higher quality and lower cost as outcomes”. A similar argument is
29 made by (Belekoukias et al., 2014), who point to the operational improvements and resulting
30 higher performance outcomes that lean techniques offer manufacturing organisations in
31 contemporary, globalised and highly competitive markets.
32
33
34
35
36
37

38 Lean manufacturing principles do not only concern a company's technical operations but also
39 its people. ILP has led to companies moving away from Tayloristic principles that encouraged
40 the separation of “thinking from doing” through the centralisation of decision-making at the top
41 of the organisational pyramid. On the contrary, lean manufacturing argues for the involvement
42 of supervisors and production workers in the decision-making process through quality circles
43 or other types of problem-solving groups and for raising their skills through training. Forrester
44 (1995: p.22) highlighted the role that knowledge plays in ensuring synergy between lean and
45 people practices: “The whole process becomes a more people-centred one, with employees
46 becoming more involved and flexible. In its simplest terms lean production has to be a people-
47 driven process, because only the employees can identify ways of improving the existing process
48 or product”.
49
50
51
52
53
54
55
56

57
58 Accordingly we posit the following hypothesis:
59
60

1
2
3 *H1: ILP have a positive impact on operational performance.*
4
5
6
7

8
9 *2.2 Lean practices and the operational intellectual capital – operational performance*
10 *relationship*
11

12 The potential for a synergetic relationship between lean practices and dimensions of OIC can
13 be addressed in the context of the KBV. According to the proponents of the KBV of the firm,
14 knowledge is the most important strategic resource that provides and sustains competitive
15 advantage (Grant, 1996, Eisenhardt and Santos, 2003). Companies need to develop value-
16 creating strategies by managing the system of complementary resources (i.e. its knowledge base
17 and lean practices). It could be argued that operations management programs and practices such
18 as lean, might not entirely fulfil the requirements of competitive advantage (valuable, rare, hard
19 to imitate or substitute). For example, the rare characteristic can be questioned: many
20 companies have adopted lean practices and developed their own production system (i.e. Volvo
21 production system) (Netland et al., 2015). However, previous research has shown that
22 implementation of lean practices such as TQM, JIT, workforce development, automation,
23 customer/supplier development and integration, enhances the operational performance making
24 the companies more competitive (Netland et al., 2015, Boscari et al., 2016, Negrão et al., 2016).
25
26
27
28
29
30
31
32
33
34

35 Accordingly, using the KBV as the theoretical lens, we argue that when ILP are coupled with
36 dimensions of OIC (which represents the company knowledge base), they both become a
37 critical source for operational and business success. Wiengarten et al. (2013) highlighted that
38 based on the RBV and OM literature, the long-term performance enhancing ability of operations
39 programs such as lean, has not been fully explored. That can be explained by the fact that the
40 impact of lean practices on performance might be complemented by other organisational
41 dimensions or practices, resulting in a complementary performance enhancing relationship
42 (Bortolotti et al., 2015). Teece (2014) defines complementary assets as resources that are
43 required to gain the benefits associated with a strategy, a technology, or an innovation. While
44 much of lean research suggests that there is a direct relationship between lean practices and
45 operational performance, Teece's approach points out that companies would need to possess
46 complementary assets to gain competitive advantage from the implementation of lean practices.
47 Accordingly based on previous literature, KBV theory and the concept of complementarity, we
48 argue that the performance impact of ILP can be enhanced through the OIC dimensions. The
49
50
51
52
53
54
55
56
57
58
59
60

subsequent sections will explore the synergetic effects between each dimension of OIC and the lean practices.

2.2.1 Lean practices and human capital

Empirical evidence suggests that human capital (HUC) is a key antecedent of operational performance (Nyberg et al., 2014). The KBV, which draws upon the elements of the resource-based view (RBV) of the firm, has been used to identify HUC as a key variable in explaining why some companies outperform others (Prajogo and Oke, 2016). HUC is the knowledge, experience, professional skills and abilities in employees (Subramaniam and Youndt, 2005). If organizations invest in educating and training their employees, their professional skills and competence should increase, resulting in better individual and organizational performance. Snell and Dean (1992) have highlighted the role of human capital, specifically skilled human resources, in the implementation of new manufacturing practices such as advanced manufacturing techniques, just-in-time, and total quality management. Such programmes are quite complex to enact within an organisation, and require knowledgeable employees. Lee et al. (2011) examined the role of intellectual capital in implementing manufacturing process innovations (MPI). Initial findings suggested that HUC did not affect MPI, however when looking at the type of MPI (incremental versus radical) the results suggested that the greater the HUC, the higher the technical performance of radical MPI projects. Their findings concur with Subramaniam and Youndt (2005), who found that HUC had no direct impact on incremental innovation capability, while it had a significant impact on radical innovation capability.

Hitt et al. (2001) examined the direct and moderating effects of HUC on strategy and performance in professional service firms. Using cross-sectional (firms) and time series data (years), they found a curvilinear relationship between human capital and performance. Building human capital can be costly and it takes time to produce substantial benefits. However, continuing investments can reap greater benefits when done in conjunction with other practices, due to the synergies achieved. Furthermore, skilled workers tend to be more confident in their abilities than unskilled ones and are more likely to adopt technological change. When a new system or technology is being applied, they utilise their experience to solve the problems that relate to implementation. The positive impact of HUC on performance has also been highlighted by Crook et al. (2011). They argue that firms need to acquire and nurture the best and brightest human capital available and keep these “assets” in the firm. They also argue for additional

1
2
3 research to explore the synergetic relationship between human capital and the use of high-
4 performance work practices and their effect on performance. Thus, we hypothesise that the
5 possession of knowledge, experience and professional skills and abilities in employees enables
6 lean practices to achieve higher levels of operational performance.
7
8
9

10
11 *H2: Manufacturing plants that are characterised by high levels of HUC gain higher operational*
12 *performance benefits from ILP, as compared to plants with low levels of HUC*
13
14

15 16 17 18 2.2.2 *Lean practices and structural capital*

19
20 The adoption of lean requires a vast amount of knowledge and information sharing. Workers
21 that display knowledge of successful lean implementation are frequently identified as
22 champions of implementation (Clegg et al., 2013). However, organisations from time to time
23 lose the human capital when employees leave or move to a different company. As such, it is
24 important that companies have systems or mechanisms to transfer knowledge from the
25 individual to the organisational level. Lee et al. (2011) point out that isolated individual
26 capabilities are not enough to effectively complete an innovative task (i.e. implementation of
27 lean practices). Information must be exchanged, in order to strengthen the organisational
28 learning capability and to fully leverage this resource.
29
30
31
32
33
34
35

36 The second form of OIC is structural capital (STC), which involves “the institutionalized
37 knowledge and codified experience residing within and utilized through database, patents,
38 manuals, structures, systems and processes, which can be conceptualized in terms of
39 organizational processes and information systems” (Subramaniam and Youndt, 2005: p.451).
40 According to Guerrero-Baena et al. (2015), structural capital is the frame and the glue of an
41 organization because it provides the tools and architecture for retaining, packaging and moving
42 knowledge along the value chain (Cabrita and Bontis, 2008). Sharing information is key to
43 developing a learning culture, where workers can access cross-departmental knowledge (Wu,
44 2008). In order to facilitate this, knowledge must be deemed valuable and companies must focus
45 on the quality of the information shared, rather than quantity. Ferdows (2006) highlighted the
46 need for the proper codification of information in order to facilitate its movement between
47 organisational units. This results in the standardisation of procedures and processes which are
48 key features in lean management (Spear and Bowen, 1999). In contrast, Secchi and Camuffo
49 (2016) propose a counterintuitive view that in lean programs, the codification of knowledge
50
51
52
53
54
55
56
57
58
59
60

1
2
3 may decrease transfer effectiveness by inhibiting local adaptation. Also, standardisation of
4 work can lead to reduced work autonomy, increase monotony and stress. On the other hand,
5 Losonci et al. (2011: p.31) state that in lean production “workers have more freedom in dividing
6 their work within their group, and they become responsible for the level of quality that they
7 provide, for improvements in that regard, and for other work-related issues”. Grove et al. (2010)
8 investigated a 13-month lean implementation in National Health Service (NHS) primary care
9 health visiting services, specifically focusing on standardisation and identification of value
10 adding activities. Their findings suggest that the lean implementation demonstrated significant
11 waste reduction in the health service. For example, standardisation enabled a reduction in the
12 variation in day-to-day activities performed by clinical staff and allowed them to focus on value
13 adding activities.
14
15
16
17
18
19
20
21
22

23 Tu et al. (2006) and Huang et al. (2008) found that information sharing and internal learning
24 have a positive impact on successful implementation of manufacturing practices. As such, STC
25 enables workers to access valuable complementary expertise, thereby leading to a more
26 successful implementation of lean practices.
27
28
29

30 Thus, we propose the following hypothesis:

31
32
33 *H3: Manufacturing plants that are characterised by high levels of STC gain higher operational*
34 *performance benefits from ILP, as compared to plants with low levels of STC*
35
36
37
38
39

40 2.2.3 Lean practices implementation and social capital

41
42 The third form of OIC is social capital (SOC) and is defined as “the knowledge embedded
43 within, available through and utilised by interactions among individuals and their networks of
44 interrelationships” (Subramaniam and Youndt, 2005: p.451). In comparison to structural
45 capital, which requires formal process and procedures, social capital does not need any
46 predetermined rules (Lee et al., 2011). According to Zhang et al. (2015), social capital reflects
47 the knowledge that develops from formal and informal interactions among employees, which
48 enables cooperation and the formation of knowledge exchange mechanisms.
49
50
51
52
53
54

55 Informal interactions among employees, allows them to reach common goals and to collaborate
56 across functional boundaries, enabling the development and implementation of new practices
57 (Lee et al., 2011). When employees are able to openly discuss problems and issues, they are
58
59
60

1
2
3 more likely to embrace knowledge about latest process developments and try new practices
4 without worrying about making mistakes (Kang and Snell, 2009). Youndt et al. (2004) state
5 that social capital helps employees to have common expected outcomes of process innovations
6 and motivates them to find solutions together, enabling a company to introduce new processes
7 frequently. Moreover, the accessibility of people in different functions facilitates interactions
8 that lead to a common understanding of the production system as a whole, rather than being
9 function based (Zhang et al., 2015).

10
11
12
13
14
15
16 Prior empirical research has shown the important role that organisational culture plays in the
17 implementation of new programmes or practices (Danese et al., 2017, Losonci et al., 2017).
18 Positive and supportive organisational culture tends to amplify the “togetherness” element of
19 the workforce. This can be regarded as an aspect of social capital because it promotes trust and
20 collaborative relationships among workers (Behara et al., 2014). More recently, Matthews and
21 Marzec (2012) found empirical support for social capital having a positive impact on quality
22 management, project management, new product development and supply chain management.
23 Similarly, Yuan et al. (2009) established that investments in social capital is an important
24 precondition to enhanced group learning and performance. When investing in lean practices, a
25 key element is employee involvement. Employees are encouraged to express their opinions and
26 feel secure in suggesting process improvements. Previous studies have labelled this type of
27 behaviour as “an open communication climate” (Tu et al., 2006) or “team psychological safety”
28 (Lee et al., 2011). Any sort of new system or practice that is being adopted will require and
29 benefit from the support of top management. Employees will therefore be less likely to fear
30 failure and will be more willing to take risks and be innovative throughout the implementation
31 process. When employees are encouraged to share errors/mistakes and openly seek resolution,
32 the new system or practice is more likely to be installed efficaciously. Having a strong
33 collaborative culture can lead to successful implementation of lean (Bortolotti et al., 2015).
34 Thus, we posit:

35
36
37
38
39
40
41
42
43
44
45
46
47
48
49
50 *H4: Manufacturing plants that are characterised by high levels of SOC gain higher operational*
51 *performance benefits from ILP, as compared to plants with low levels of SOC*

52
53
54 Accordingly, this study examines the effects of ILP on operational performance by considering
55 the moderating role of individual dimensions of OIC. Figure 1 depicts the proposed research
56 framework based on the theoretical advancements presented.

57
58

3. Methodology

3.1 Sample and procedures

The empirical data used for this study was drawn from the fifth round of the Global Manufacturing Research Group (GMRG) survey project, collected between 2011 and 2014. The Global Manufacturing Research Group (GMRG) (www.gmrg.org) is an international community of researchers who are rigorously studying the improvement of manufacturing supply chains worldwide. The instrument was designed to assess and improve manufacturing and supply chain practices worldwide and has been in use since 1985 in many studies (Whybark, 1997). The survey has been conducted in several rounds and in each round, a common questionnaire for all countries is developed based on well-grounded theories, group members meetings, feedback from previous rounds and industrial interviews (Li et al., 2018). The questionnaire has been translated and back-translated by researchers in each country, in order to ensure equivalency, validity and reliability of the translated surveys (Kull et al., 2014). The unit of analysis is the manufacturing site or plant, and all data are collected from plant managers as key informants within that site, who often consult others in their firm. These managers are targeted since they are deemed to possess a comprehensive knowledge of the plant's operations, in addition to having insight into related functions. The managers are advised to solicit input from other functions, such as marketing and finance, when required.

In order to ensure comparable samples were collected from each country, detailed information related to the questionnaire administration was provided. Each data collector received a GMRG start-up package that contained the questionnaire, the data gathering sheet (where data has to be stored), the validation sheet (where data quality can be assessed) and the methodology sheet (which described how data collection has been developed). The data collected from various countries were grouped by a central data manager for incorporation into the central database. Prior to inclusion, each data collector performed a check of the quality of the data gathered in terms of incomplete questionnaires, missing data, unreliable answers (i.e. answers outside the provided scales) and the country codes. Data was collected by individual members of the GMRG, who are requested to apply the most appropriate approach and the most suitable population frame depending on the country-specific circumstances (Whybark, 1997). This flexibility is afforded to the researchers owing to the complexity and length of the questionnaire, often requiring the key respondent to consult with other individuals within the firm, or the

1
2
3 compilation of historical data and the calculation of indices. Most questionnaires were
4 administered during an on-site personal interview (43%), followed by internet completion
5 (29%) and mail surveys (23%) (Schoenherr and Narasimhan, 2012).
6
7

8
9 The questionnaire consists of one core module (providing constructs related to demographics
10 and competitive environment) plus four other modules on supply chain management,
11 sustainability, and innovation and facility culture. In addition to the core module of the survey,
12 the data gatherers were free to select specific modules that they were interested in. The fifth
13 round of the GMRG survey had 987 respondents in total, however given the focus of this study
14 on the interaction between OIC components and ILP, we only used data where survey
15 respondents completed the modules which contained our variables of interest. This reduced our
16 sample size to a total of 528 plant responses. Thus, given the extensive coverage over 10
17 countries from all the major continents ensures that the GMRG data is appropriate for
18 generalising about the synergetic effects between ILP and OIC dimensions.

28 and industry.
29

30
31 --- Insert Table I About here --
32
33

34 In order to test for non-response bias, the responses from early and late respondents were
35 compared on selected variables (i.e. ILP, performance measures and OIC variables) using
36 independent samples t-tests (Schoenherr and Narasimhan, 2012). This test assumes that late
37 respondents are used as proxy for non-respondents (Armstrong and Overton, 1977). The results
38 show that there is no statistically significant difference between these two groups, indicating
39 that the potential non-response bias is not evident. Given the limitations of this test (Wright and
40 Armstrong, 2008) and the fact that we could not contact individuals that did not respond at all
41 (due to unavailability of this information), we decided to further corroborate this assessment,
42 by testing for item non-response bias (Wagner and Kemmerling, 2010). This approach can be
43 compared to the more rigorous method of contacting non-respondents. Independent samples t-
44 tests were applied to compare questionnaires from individuals that provided answers to the all
45 survey questions to those that only partially completed the survey (with the latter serving as a
46 proxy for non-respondents and not being included in the final sample). The results yielded non-
47 significant differences between complete and incomplete surveys, further reinforcing that non-
48 response bias is not a serious concern.

3.2 Measures: reliability and validity

To measure ILP, respondents were asked to indicate the extent to which their plant has invested resources (money, time and/or people) in the previous two years in these initiatives. The measures related to the investments in lean practices have been used and tested in previous research. Our data reflect the extent that lean practices proposed by Shah and Ward (2007) are perceived in the plant as follows: quality management programs (i.e. TQM, six sigma) (Cua et al., 2001), cost reduction programs (i.e. target costing) (Modarress et al., 2005), manufacturing lead time reduction programs (Jayaram et al., 2008, Kull et al., 2014), planning/scheduling processes and methods (Bortolotti et al., 2015), processing technologies (e.g. automation, advanced manufacturing technologies) (Narasimhan et al., 2006), flexible workforce (Jayaram et al., 2008, Bortolotti et al., 2015), supplier development (Narasimhan et al., 2006), workforce training and development (Bortolotti et al., 2015), integrating manufacturing and design processes (Narasimhan et al., 2006, Jayaram et al., 2008), plant information flows automation (Kull et al., 2014), customer service, customer process integration and supplier process integration (Narasimhan et al., 2006, Bortolotti et al., 2015). All the lean practices measures used have been identified as part of lean bundles the current extensive literature reviews of Jasti and Kodali (2015) and (Negrão et al., 2016).

The operational performance construct was adopted from Melnyk et al. (2004), Cua et al. (2001) and was measured across the selected dimensions of cost, quality, delivery and flexibility. The variable is a second order construct, with no modification indices used, that measures firms 'operational capabilities compared to major competitor(s) on the 7-point Likert scale (1- far worse to 7- far better). OIC was conceptualised in dimensions of social capital (4 items), structural capital (4 items) and human capital (4 items). The items for the human, social and structural capital were developed based on studies by Menor et al. (2007) and Subramaniam and Youndt (2005). The respondents were asked to indicate their level of agreement with multiple statements on a scale of one (strongly disagree) to seven (strongly agree). Two control variables were added: plant size and industry type. Shah and Ward (2003) suggest that large plants are likely to invest in lean practices more extensively compared to small plants. In addition, ILP are particularly relevant to certain industry types, such automotive, given the repetitive processes and high volumes (Hines et al., 2004). Hence plant size and industry type were included in order to increase the generalisability of this study.

4. Results

4.1 Scale validity

Confirmatory factor analysis was used to simultaneously validate the measures of all variables used in the study. The results are presented in Table II. Convergent validity was assessed by comparing the items' coefficients and their standard error. Results indicate that each coefficient was greater than twice its associated standard error (Farrell and Rudd, 2009). Cronbach alpha values have been calculated to test the reliability (internal consistency) of the proposed latent variables. All values in Table II, column 1 are above the commonly used cut-off value with a minimum of 0.7 indicating reliable measures (Raykov and Marcoulides, 2011).

--Insert Table II About here--

A comparison of the goodness-of-fit values against the Hu and Bentler (1999) thresholds indicate that this model is satisfactory (See table II for details). In addition, the ratio of chi-square to degrees of freedom of 2.209 (χ^2/df) is satisfactory (Hooper et al. (2008)). Subsequently, it can be concluded that the measurement items represent the underlying factor structure in a conclusive manner (Wang and Wang, 2012).

4.2 Convergent reliability and inter-factor correlations

Composite reliability statistics indicated strong construct reliability in each case; all values are well above 0.7 (Fornell and Larcker, 1981). The results established convergent validity and unidimensionality for each construct, as all item loadings (lambdas) are highly significant (all t-values are >2.0) (See Table II). The results also indicated acceptable discriminant validity for the measures at both the construct and item levels. We interpret these results as strong, especially given the multi-country, multi-industry and highly varying size of the organizations represented in this data set. It is also customary to report inter-item correlations. This is presented in Table III. Discriminant validity was confirmed through testing inter-factor correlations. Results indicate adequate inter-factor correlations (Schreiber et al., 2006)

--Insert Table III About here --

4.3 Common method variance

1
2
3 Common method variance is a crucial question when both the dependent and focal explanatory
4 variables are perceptual measures derived from the same respondent (Conway and Lance,
5 2010). The post hoc Harman one-factor analysis was performed and one-factor analysis
6 accounts for only 30.696% % of variance (Podsakoff et al., 2003). The results of the test,
7 provide evidence that common method variance does not appear to pose a serious threat to our
8 study.
9
10
11
12

13 14 *4.4 Measurement equivalence*

15
16 Finally, since the dataset used in this study was collected in multiple countries, the issue of
17 measurement equivalence had to be addressed. More specifically, we examined whether or not
18 the constructs via their related scales are invariant across countries (Malhotra and Sharma,
19 2008). Measurement equivalence refers to whether or not measurement items, under varying
20 conditions and phenomenon, yield the same attributes. It is critical to assess measurement
21 invariance across groups in order to be able to make valid scientific claims and conclusions
22 (Malhotra and Sharma, 2008). Only if measurement equivalence is ensured across countries
23 then the collected datasets can be either combined or compared with each other. A number of
24 recent studies have confirmed measurement equivalence in the GMRG dataset through various
25 tests (e.g. Schoenherr and Narasimhan, 2012; Wiengarten et al., 2011).
26

28
29
30
31
32
33
34

35 *4.5 OLS regression analyses*

36
37 To test the proposed model, we used three OLS regression analyses (Wiengarten et al., 2013,
38 Chavez et al., 2015, Durach and Wiengarten, 2017). The analysis was conducted in three
39 separate models reflecting the three interaction terms (level of ILP and social capital; level of
40 ILP and human capital and level of ILP and structural capital). In the first step of the OLS
41 analysis, the control variables, industry type and plant size were introduced. In the second step,
42 the level of ILP and moderators: social capital (Model I), human capital (Model II), and
43 structural capital (Model III), were introduced. In the third step, the interaction terms were
44 added (Model I: ILP and SOC; Model II: ILP and HUC; Model III: ILP and STC). Prior to
45 carrying out the OLS analysis the data was checked in terms of linearity and multicollinearity
46 (Kennedy, 2003). Firstly, the variance inflation factors (VIFs) were calculated and are included
47 in table IV. The resulting VIFs indicate that multicollinearity is not apparent.
48
49
50
51
52
53
54
55
56

57 --Insert Table IV About here--
58
59
60

1
2
3 In H1 it was hypothesised that ILP have a significant positive impact on operational
4 performance. Previous empirical studies showed mixed results for lean practices
5 implementation on operational performance. In terms of contingency theory, our analyses
6 reveal that both industry type and plant size had no significant effect on operational
7 performance. The results presented in Table IV indicate that ILP and the dimensions of OIC do
8 significantly improve operational performance. This finding concurs with Menor et al. (2007)
9 who found that investments into OIC augment operational performance. Accordingly, we found
10 support that all three dimensions of OIC have a positive impact on operational performance.
11
12
13
14
15
16

17
18 In H2, H3 and H4 we posited that ILP have a stronger positive impact on operational
19 performance when combined with high levels of investments in social, human and structural
20 capital. To analyse the synergetic effects between the ILP and OIC, interaction terms were
21 calculated by adding the two-way interaction term to the OLS Models I, II and III.
22
23
24

25
26 In model I, the addition of the two-way interaction term contributed to a significant change in
27 the variance explained (R^2 adj. = 0.323, $p = 0.000$), however the interaction term was not
28 significant ($B = 0.071$, $p = 0.052$). The results reveal no synergetic effects between the ILP and
29 human capital. For model II adding the two-way interaction term contributed to a significant
30 change in the variance explained (R^2 adj. = 0.292, $p = 0.000$), and the interaction term was
31 significant ($B = 0.109$, $p < 0.05$). To interpret this finding the significance of the slopes were
32 calculated at low (one standard deviation below the mean) and high (one standard deviation
33 above the mean) levels of STC (Preacher et al., 2006, Dawson, 2014). The results revealed that
34 ILP were strongly associated with higher operational performance when the levels of STC were
35 high, than when the levels of STC were low (see Figure 2). In other words, ILP have a higher
36 payoff rate when the firm is also increasing the level of structural capital. Accordingly, there is
37 evidence of synergetic effects between ILP.
38
39
40
41
42
43
44
45
46

47
48 Finally, in OLS Model III the addition of the two-way interaction term contributed to a
49 significant change in the variance explained (R^2 adj. = 0.361, $p = 0.000$), and the interaction
50 term was significant ($B = 0.076$, $p < 0.05$). To interpret this finding the significance of the
51 slopes were calculated at low (one standard deviation below the mean) and high (one standard
52 deviation above the mean) levels of SOC (Preacher et al., 2006, Dawson, 2014). The results
53 revealed that ILP were strongly associated with higher operational performance when the levels
54 of SOC were high, than when the levels of SOC were low (see figure 3). In other words, ILP
55
56
57
58
59
60

1
2
3 have a higher payoff rate when the firm is also increasing the level of social capital. Thus, we
4 also found evidence of synergetic effects between ILP and SOC.

12
13

14 **4. Discussion and implications**

15
16
17 The objective of this study was to empirically test if the operational intellectual capital (in terms
18 of human, structural and social) contribute to the efficacy of ILP. Although partial support was
19 found for the hypothesised relationships (three out of four hypotheses were supported), our
20 findings provide a significant contribution to lean management theory in adopting a
21 knowledge-based view of the firm. The significance of these contributions is discussed below.
22
23

24
25
26 In exploring the research question of this study, we have made a number of theoretical
27 contributions. The literature review has identified several studies that investigated the impact
28 of lean practices on operational performance (Chavez et al., 2015, Boscari et al., 2016, Danese
29 et al., 2017). Our study further underpins the argument that lean practices investments lead to
30 higher operational performance, specifically in terms of cost, quality, flexibility and delivery
31 dimensions. This finding is compatible with the “cumulative” perspective (Ferdows and De
32 Meyer, 1990) which suggests that high operational performance is achieved by pursuing
33 multiple competitive priorities. Our results suggest that ILP enable companies to outperform
34 their competitors on multiple operational performance dimensions, rather than focusing on
35 individual performance objectives.
36
37

38
39
40 Companies introduce innovative practices such as lean practices in anticipation of improving
41 performance. Negrão et al. (2016) highlighted that most studies of lean practices focus on
42 testing their impact on operational performance, but that very few attempt to explain how this
43 impact can be augmented. Our study addresses this gap and provides a plausible explanation of
44 this gap. We argue that OIC, which represents the organisational learning capability, can
45 enhance ILP. Our findings of moderation effects (for two out of three OIC dimensions)
46 reinforces the role of OIC as a mechanism that enhances operational performance in ILP.
47
48 Accordingly, our research offers an additional important contribution to the lean literature by
49 testing the moderating role of OIC.
50
51
52
53
54
55
56
57
58
59
60

1
2
3 This study also contributes to the intellectual capital literature by providing insights into the
4 individual effects of human, structural and social capital on operational performance (Wang et
5 al., 2014, Prajogo and Oke, 2016, Zhang et al., 2017) and how these dimensions can be used to
6 enhance the efficacy of lean practices (Hadid et al., 2016). We did not find evidence of
7 interaction effects between the ILP and human capital. This is somewhat surprising, as human
8 capital, which represents knowledge, experience and professional skills, would be expected to
9 act as a key variable in rolling out a lean production system. Our findings concur with other
10 studies, in that HUC positively impacts on operational performance (Wang et al., 2014, Prajogo
11 et al., 2016); however no empirical support was found for an enhancement effect on the efficacy
12 of ILP. A possible explanation for this result is provided by considering the findings of
13 Subramaniam and Youndt (2005) who empirically tested the impact of human capital on the
14 innovation capabilities and found no direct impact on incremental innovation but a significant
15 impact on radical innovation. Accordingly, we posit that ILP result in incremental innovation
16 capability, which “build on and reinforce the applicability of the existing knowledge base”
17 (Abernathy and Clark, 1985: p.5). The implication is that human capital will not enhance the
18 efficacy of incremental improvements, for example lean practices implementation. Another
19 explanation could relate to the maturity level of lean investments. In our study we did not
20 measure the degree of lean maturity; however if companies are just starting to invest in lean
21 practices, then we would expect human capital to play an important role in the efficacy of ILP.
22 As the lean practices mature, the work methods become standard and routine-based, thus
23 reducing the synergies between HUC and ILP.
24
25
26
27
28
29
30
31
32
33
34
35
36
37
38
39

40 Furthermore, we found that structural and social capital have a positive impact on operational
41 performance and enhance the efficacy of lean practices (Hsu and Wang, 2012, Sparrow and
42 Otaye-Ebede, 2014). Both, STC and SOC, acted as moderators in the lean practices and
43 operational performance relationship. These results provide further understating of the effects
44 of STC and SOC on performance (Subramaniam and Youndt, 2005, Menor et al., 2007) as well
45 as their augmentation role in lean investments. Hence, researchers could consider both the direct
46 and moderating effects of the OIC when investigating lean investments.
47
48
49
50
51
52

53 Structural capital has been conceptualised in terms of the institutionalised knowledge and
54 codified experience residing within a company. This allows knowledge to move across the
55 value chain and results in the development of standardised processes and procedures that are
56 shared across departmental units. The STC creates the characteristics of a self-directed learning
57 environment and enables companies to replicate knowledge embedded in practices by utilising
58
59
60

1
2
3 physical organization-level repositories such as databases, archives and SOPs. Replication is a
4 key element of lean production systems that enhances standardisation (Bonavia and Marin-
5 Garcia, 2011). Having a standardised procedure/ process creates a starting point for companies
6 to continuously improve. It can reduce the cost and time of the implementation process. Secchi
7 and Camuffo (2016) conducted a longitudinal study of the process of rolling out lean production
8 systems. Their findings offer a counterintuitive view on the effectiveness and efficiency of lean
9 implementation and point out that “lean roll-outs are learning and discovery processes where
10 paradoxically codification and structural differentiation are not necessarily conducive to better
11 outcomes” (Secchi and Camuffo, 2016: p.82) This concurs with the view that ambidextrous
12 learning is derived from intellectual capital architectures as a result of unique configurations of
13 the different forms of intellectual capital (Kang and Snell, 2009). Our study did not assess the
14 ambidextrous learning through configurations of OIC; however we found empirical evidence
15 that STC through enhanced knowledge replication increases the efficacy of ILP. We argue that
16 companies that share valuable knowledge and promote internal learning will achieve higher
17 operational performance. As such, STC enables workers to access valuable complementary
18 expertise, thereby leading to more successful ILP (Tu et al., 2006, Huang et al., 2008).

19
20
21
22
23
24
25
26
27
28
29
30
31 Social capital, on the other hand, does not rely on formal processes and procedures or any
32 predetermined operating rules. We defined social capital as the knowledge available through
33 interactions among individuals, degree of accessibility, and openness of communication.
34 Recent studies have highlighted the role of social capital and organisational culture in
35 increasing operational performance (Danese et al., 2017, Losonci et al., 2017, Wiengarten et
36 al., 2017). This study provides a deeper understanding into its role as we specifically
37 investigated the combined impact of SOC and ILP on operational performance. Our results
38 show that the impact of ILP on operational performance is increased in the presence of SOC.
39 Previous studies established the role of SOC in improving mass customisation and product
40 innovation capabilities (Zhang et al., 2015, Wiengarten et al., 2017). We thus contribute to this
41 area of the literature by confirming the SOC’s pivotal role for the efficacy of ILP.

42
43
44
45
46
47
48
49
50
51 From a managerial standpoint, this study provides guidelines for managers on how to leverage
52 OIC to enhance the return of ILP. We argue that firms consider investing in OIC to increase
53 their operational performance. Human capital development is important, especially when
54 companies seek to conduct radical improvements. Focusing on job enlargement and enrichment
55 will create knowledge workers, that would be better equipped in dealing with innovative
56
57
58
59
60

1
2
3 projects. Training programmes should be developed to share best practices and dispense
4 knowledge through the organisation.
5
6

7 When companies select, recruit, train and reward employees, they should focus not only on
8 their individual skills or functional expertise, but also on their ability to share it with other team
9 members, in order to create a collaborative culture. Acceptance of knowledge from others is
10 another important aspect of change implementation (Beer and Eisenstat, 2000). Companies
11 need to design proper channels of knowledge collection and dissemination (Ferdows, 2006).
12 This is where structural capital plays an important role in enhancing ILP. Our results reveal that
13 STC positively impacts operational performance and companies ILP have a higher payoff rate
14 in terms of operational performance, when the company is also increasing their STC levels.
15 These findings corroborate with Tu et al. (2006) and highlight the need for firms to develop an
16 open learning culture, where workers can access cross-departmental knowledge as well as
17 knowledge from external partners (suppliers and customers). This type of structural relationship
18 leads to better coordination and implementation of lean practices across departments and
19 companies.
20
21

22 Our findings provide strong evidence of the importance of social capital to enhance the efficacy
23 of ILP. Sawhney et al. (2010) state that the reason why not all companies experience improved
24 operational performance from lean practices, is that they do not focus on the sustainability
25 aspect of change, specifically referring to the lack of know-how. In this regard we emphasise
26 that social capital is an important enabler for employees to share ideas and cooperate in know-
27 how creation. The degree of accessibility of people, allows them to comfortable approach one
28 another and discuss problems and issues openly. Inherently, it creates psychological safety and
29 provides a strong foundation for knowledge exchange and combination within a firm. Social
30 capital impacts the ILP, therefore managers need to encourage informal conversations among
31 employees in the plant as a form of sharing knowledge and organise events where people can
32 openly discuss their experiences. These events can therefore act as catalysts in enhancing
33 interrelationships and contribute to successful lean practices implementation.

55 **5. Limitations, further research and conclusion**

56
57 This study has some limitations. Firstly, we suggest further refining the measurement items of
58 OIC to holistically capture the dimensions of operational intellectual capital. Secondly, we
59
60

1
2
3 investigated the impact of ILP on operational performance; however, the use of additional
4 performance measures, such as financial and market related performance could be merited.
5
6 Thirdly, the existing literature on lean practices does not address the innovativeness of lean
7 practices and how these practices should be managed in different ways. Thirdly, our analysis
8 provides limited theoretical insights into how to use OIC resources differently given how far a
9 company has progressed on its lean journey. It may very well be the case that if a company is
10 new to lean implementation, then this would be viewed as radical innovation and as such,
11 human capital would play an important role in its implementation. If the company has
12 progressed on its lean journey, then the STC and SOC might provide stronger support in
13 increasing the efficacy of lean practices. Thus, further investigation of the relationship between
14 the maturity level of the lean practices and the level of investments in OIC is worthy of
15 consideration. Fourthly, our study did not consider the interrelationships among HUC, STC and
16 SOC. Future studies could investigate how the interaction between these dimensions, yield the
17 highest impact on the efficacy of ILP. In addition, other contextual variables should be used in
18 order to see if the impact of OIC on the efficacy of ILP varies across them. Finally, our sample
19 framing design is likely to be non-random. Although we have the benefits of a large-scale cross-
20 country dataset, the data collection is subject to this limitation, which needs to be considered
21 when interpreting the results.

31
32
33

34
35 Overall, this study extends our understating of how companies enhance the effect ILP have on
36 operational performance. We examined the effects of ILP on operational performance by
37 considering the moderating role of OIC. To test our hypotheses, we used three OLS regression
38 analyses. The analysis was conducted in three separate models reflecting the three interaction
39 terms (level of ILP and human capital; level of ILP and structural capital and level of ILP and
40 social capital). Our results confirm the impact of social and structural capital on ILP and raising
41 operating performance, hence hypotheses H2 and H3 are confirmed. Human capital interaction
42 with ILP on operational performance did not show a significant effect.

50 This paper makes three key contributions to operations management literature. Firstly, this
51 study extends our understanding of how some organisations achieve superior performance by
52 leveraging individual dimensions of OIC. Secondly, we add valuable insights to the lean
53 literature by testing the synergetic effects between elements of the operational intellectual
54 capital and the ILP (Sparrow and Otaye-Ebede, 2014). The results shed further understanding
55 of the complex relationship between ILP and operational performance. Thirdly, from a practical
56 perspective our research offers managers empirical evidence related to the effect of knowledge

management on operational performance. Specifically our study highlights how the individual elements of the OIC can be used to augment operational performance generated through ILP (Wu, 2008, Wang et al., 2014).

	Employees in this plant are highly skilled in their respective jobs.	0,808	0,048	20,392	***
$\chi^2=2.209<3$, $GFI=0.888$, $NFI=0.892$, $IFI=0.938$. $CFI=0.937$, all ≈ 0.9 , $REMSA=0.048$ has to be <0.05 , $PCLOSE = 0,828$ has to be close to 1					

Table III. Inter-factor correlations

Constructs	Mean	(1)	(2)	(3)	(4)	(5)
Operational performance (1)	2.69	0.589 (0.347)				
Investments in Lean Practices (2)	4.34	0.475**	0.405 (0.164)			
Human Capital (3)	5.08	0.507**	0.440**	0.689 (0.475)		
Structural Capital (4)	3.88	0.450**	0.432**	0.681**	0.675 (0.456)	
Social Capital (5)	5.22	0.486**	0.323**	0.639**	0.607**	0.646 (0.418)

Value on the diagonal is the AVE and its square root in brackets; **Correlation is significant at the .001 level (2-tailed)

Table IV: OLS analysis for moderation effects

	Model 1	Model 2	Model 3
	Human capital	Structural capital	Social capital
Variable			
Step 1. Control variables			
Industry Type	0.012 (0.870)	0.012 (0.870)	0.012 (0.870)
Plant Size	-0.010 (0.821)	-0.010 (0.821)	-0.010 (0.821)
Step 2. Independent variables			
ILP	0.471**	0.471**	0.471**
Step 3. Moderators			
HUC	0.471**		
STC		0.295**	
SOC			0.359**
Step 4. Interactions			
ILP * HUC	0.071(0.052)		
ILP * STC		0.109(0.004)	
ILP * SOC			0.076(0.039)
Step 1 Rsquare Change/Sig.	0.000 (0.940)	0.000 (0.940)	0.000 (0.940)
Step 2 Rsquare Change/Sig.	0.218 **	0.218 **	0.218 **
Step 3 Rsquare Change/Sig.	0.107 **	0.069 **	0.114 **
Step 4 Rsquare Change/Sig.	0.005 (0.052)	0.011 (0.004)	0.005 (0.039)
Max VIF	1.304	1.331	1.190
R	0.574	0.546	0.581
Adjusted R2	0.323	0.292	0.361
Sig	0.000	0.000	0.000
Outcome	H2 not supported	H3 supported	H4 Supported

Notes: **Significant at the 0.01 level
